FUEL OIL

They are derived from petroleum, prepared by mixing heavy fractions (main distillation and conversion processes) with diluents (light distillates) until the quality requirements required for use as fuel are met

The main quality standards in which Fuel Oil is rated, regardless of its class are the following:

- * **Specific Weight:** It is used in the calculation of weight / volume ratios.
- * **Viscosity:** Defines the fuel atomization conditions and the characteristics of the injection system.
- * **Flash point:** It is of vital importance because of the legal requirements regarding safety in handling and storage.
- * **Carbon residue:** Gives a measure of the tendency of the fuel to form carbon deposits.
- * **Sulfur content:** Allows compliance with environmental regulations.
- Metal content: Causes corrosion and maintenance problems in furnaces and boilers of users.
- * **Stability:** Determines the storage time of the product.
- * **Sediment:** Excessive amounts of sediment can clog burner filters and nozzles.
- * **Ashes:** The amount of ashes formed in combustion must be low to avoid difficulties in furnaces and boilers.
- * **Calorific Power:** Amount of heat produced by the fuel as a result of total combustion.

FUEL OIL CLASSES

Fuel oil is classified into six classes, listed from 1 to 6, according to its boiling point, its composition and its use. The boiling point, which varies from 175 to 600 ° C; the length of the carbon chain, from 9 to 70 atoms; and the viscosity increases with the number of carbons in the molecule, so the heaviest must be heated to flow. The price in the global market generally decreases as the number increases.
